Forklift Brakes

Forklift Brake - A brake where the friction is supplied by a set of brake pads or brake shoes that press against a rotating drum unit referred to as a brake drum. There are some specific differences between brake drum types. A "brake drum" is commonly the explanation given if shoes press on the inner surface of the drum. A "clasp brake" is the term used to be able to describe if shoes press against the exterior of the drum. Another type of brake, known as a "band brake" utilizes a flexible belt or band to wrap all-around the exterior of the drum. Whenever the drum is pinched in between two shoes, it could be called a "pinch brake drum." Similar to a standard disc brake, these kinds of brakes are rather rare.

Early brake drums, prior to the year 1995, needed to be constantly adjusted to be able to compensate for wear of the shoe and drum. "Low pedal" can result if the needed adjustments are not carried out sufficiently. The motor vehicle can become hazardous and the brakes can become ineffective if low pedal is mixed along with brake fade.

There are quite a few various Self-Adjusting systems utilized for braking offered today. They can be classed into two separate categories, the RAI and RAD. RAI systems are built in systems which help the tool recover from overheating. The most well known RAI manufacturers are Bendix, Lucas, Bosch and AP. The most famous RAD systems consist of Ford recovery systems, Volkswagen, VAG, AP and Bendix.

The self adjusting brake will usually only engage when the forklift is reversing into a stop. This method of stopping is acceptable for use where all wheels use brake drums. Disc brakes are utilized on the front wheels of vehicles these days. By operating only in reverse it is less probable that the brakes would be adjusted while hot and the brake drums are expanded. If adapted while hot, "dragging brakes" can happen, which increases fuel expenditure and accelerates wear. A ratchet mechanism which becomes engaged as the hand brake is set is one more way the self adjusting brakes could operate. This means is only suitable in applications where rear brake drums are used. When the emergency or parking brake actuator lever exceeds a specific amount of travel, the ratchet improvements an adjuster screw and the brake shoes move toward the drum.

There is a manual adjustment knob situated at the bottom of the drum. It is usually adjusted through a hole on the opposite side of the wheel and this involves getting underneath the vehicle along with a flathead screwdriver. It is of utmost importance to be able to move the click wheel properly and tweak every wheel equally. If unequal adjustment happens, the vehicle could pull to one side during heavy braking. The most efficient way so as to ensure this tedious task is done carefully is to either lift each and every wheel off the ground and spin it manually while measuring how much force it takes and feeling if the shoes are dragging, or give every\each and every one the same amount of manual clicks and then do a road test.
